Linux Commands

Basic Commands

1. pwd — When you first open the terminal, you are in the home directory of your user. To know which directory you are in, you can use the "**pwd**" command. It gives us the absolute path, which means the path that starts from the root. The root is the base of the Linux file system. It is denoted by a forward slash(/). The user directory is usually something like "/home/username".

```
nayso@Alok-Aspire:~$ pwd
/home/nayso
```

2. ls — Use the "ls" command to know what files are in the directory you are in. You can see all the hidden files by using the command "ls -a".

```
nayso@Alok-Aspire:~$ ls
                  itsuserquide.desktop
Desktop
                                        reset-settings
                                                            VCD_Copy
Documents
                  Music
                                        School Resources
                                                            Videos
Downloads
                                        Students Works 10
                  Pictures
examples.desktop
                  Public
                                        Templates
GplatesProject
                  Qgis Projects
                                        TuxPaint-Pictures
```

3. cd — Use the "cd" command to go to a directory. For example, if you are in the home folder, and you want to go to the downloads folder, then you can type in "cd Downloads". Remember, this command is case sensitive, and you have to type in the name of the folder exactly as it is. But there is a problem with these commands. Imagine you have a folder named "Raspberry Pi". In this case, when you type in "cd Raspberry Pi", the shell will take the second argument of the command as a different one, so you will get an error saying that the directory does not exist. Here, you can use a backward slash. That is, you can use "cd Raspberry\ Pi" in this case. Spaces are denoted like this: If you just type "cd" and press enter, it takes you to the home directory. To go back from a folder to the folder before that, you can type "cd"." The two dots represent back.

```
nayso@Alok-Aspire:~$ cd Downloads
nayso@Alok-Aspire:~/Downloads$ cd
nayso@Alok-Aspire:~$ cd Raspberry\ Pi
nayso@Alok-Aspire:~/Raspberry Pi$ cd ..
nayso@Alok-Aspire:~$
```

4. mkdir & rmdir — Use the **mkdir** command when you need to create a folder or a directory. For example, if you want to make a directory called "DIY", then you can type "**mkdir DIY**". Remember, as told before, if you want to create a directory named "DIY Hacking", then you can type "mkdir **DIY**\ **Hacking**". Use **rmdir** to delete a directory. But **rmdir** can only be used to delete an empty directory. To delete a directory containing files, use **rm**.

```
nayso@Alok-Aspire:~/Desktop$ ls
nayso@Alok-Aspire:~/Desktop$ mkdir DIY
nayso@Alok-Aspire:~/Desktop$ ls
DIY
nayso@Alok-Aspire:~/Desktop$ rmdir DIY
nayso@Alok-Aspire:~/Desktop$ ls
nayso@Alok-Aspire:~/Desktop$ ls
```

5. rm - Use the **rm** command to delete files and directories. Use "**rm** -**r**" to delete just the directory. It deletes both the folder and the files it contains when using only the **rm** command.

```
nayso@Alok-Aspire:~/Desktop$ ls
newer.py New Folder
nayso@Alok-Aspire:~/Desktop$ rm newer.py
nayso@Alok-Aspire:~/Desktop$ ls
New Folder
nayso@Alok-Aspire:~/Desktop$ rm -r New\ Folder
nayso@Alok-Aspire:~/Desktop$ ls
nayso@Alok-Aspire:~/Desktop$ ls
```

6. touch — The **touch** command is used to create a file. It can be anything, from an empty txt file to an empty zip file. For example, "**touch new.txt**".

```
nayso@Alok-Aspire:~/Desktop$ ls
nayso@Alok-Aspire:~/Desktop$ touch new.txt
nayso@Alok-Aspire:~/Desktop$ ls
new.txt
```

7. man & --help — To know more about a command and how to use it, use the man command. It shows the manual pages of the command. For example, "man cd" shows the manual pages of the cd command. Typing in the command name and the argument helps it show which ways the command can be used (e.g., cd -help).

```
User Commands
TOUCH(1)
                                                                     TOUCH(1)
NAME
       touch - change file timestamps
SYNOPSIS
       touch [OPTION]... FILE...
DESCRIPTION
      Update
              the
                   access and modification times of each FILE to the current
       time.
       A FILE argument that does not exist is created empty, unless -c or
       is supplied.
       A FILE argument string of - is handled specially and causes touch to
       change the times of the file associated with standard output.
       Mandatory arguments to long options are mandatory for short options
       too.
              change only the access time
 Manual page touch(1) line 1 (press h for help or q to quit)
```

8. cp — Use the **cp** command to copy files through the command line. It takes two arguments: The first is the location of the file to be copied, the second is where to copy.

```
nayso@Alok-Aspire:~/Desktop$ ls /home/nayso/Music/
nayso@Alok-Aspire:~/Desktop$ cp new.txt /home/nayso/Music/
nayso@Alok-Aspire:~/Desktop$ ls /home/nayso/Music/
new.txt
```

9. mv — Use the mv command to move files through the command line. We can also use the mv command to rename a file. For example, if we want to rename the

file "text" to "new", we can use "mv text new". It takes the two arguments, just like the cp command.

```
nayso@Alok-Aspire:~/Desktop$ ls
new.txt
nayso@Alok-Aspire:~/Desktop$ mv new.txt newer.txt
nayso@Alok-Aspire:~/Desktop$ ls
newer.txt
```

10. locate — The **locate** command is used to locate a file in a Linux system, just like the search command in Windows. This command is useful when you don't know where a file is saved or the actual name of the file. Using the -i argument with the command helps to ignore the case (it doesn't matter if it is uppercase or lowercase). So, if you want a file that has the word "hello", it gives the list of all the files in your Linux system containing the word "hello" when you type in "**locate -i hello**". If you remember two words, you can separate them using an asterisk (*). For example, to locate a file containing the words "hello" and "this", you can use the command "**locate -i *hello*this**".

```
nayso@Alok-Aspire:~$ locate newer.txt
/home/nayso/Desktop/newer.txt
nayso@Alok-Aspire:~$ locate *DIY*Hacking*
/home/nayso/DIY Hacking
```

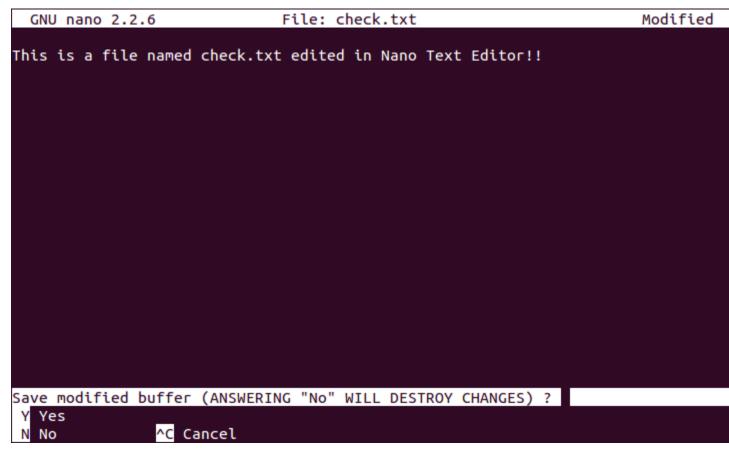

Intermediate Commands

1. echo — The "**echo**" command helps us move some data, usually text into a file. For example, if you want to create a new text file or add to an already made text file, you just need to type in, "**echo hello, my name is alok** >> **new.txt**". You do not need to separate the spaces by using the backward slash here, because we put in two triangular brackets when we finish what we need to write.

2. cat — Use the cat command to display the contents of a file. It is usually used to easily view programs.

```
nayso@Alok-Aspire:~/Desktop$ echo hello, my name is alok >> new.txt
nayso@Alok-Aspire:~/Desktop$ cat new.txt
hello, my name is alok
nayso@Alok-Aspire:~/Desktop$ echo this is another line >> new.txt
nayso@Alok-Aspire:~/Desktop$ cat new.txt
hello, my name is alok
this is another line
```

3. nano, vi, jed — nano and vi are already installed text editors in the Linux command line. The nano command is a good text editor that denotes keywords with color and can recognize most languages. And vi is simpler than nano. You can create a new file or modify a file using this editor. For example, if you need to make a new file named "check.txt", you can create it by using the command "nano check.txt". You can save your files after editing by using the sequence Ctrl+X, then Y (or N for no). In my experience, using nano for HTML editing doesn't seem as good, because of its color, so I recommend jed text editor. We will come to installing packages soon.

4. sudo — A widely used command in the Linux command line, **sudo** stands for "SuperUser Do". So, if you want any command to be done with administrative or

root privileges, you can use the **sudo** command. For example, if you want to edit a file like **viz. alsa-base.conf**, which needs root permissions, you can use the command – **sudo nano alsa-base.conf**. You can enter the root command line using the command "**sudo bash**", then type in your user password. You can also use the command "**su**" to do this, but you need to set a root password before that. For that, you can use the command "**sudo passwd**"(not misspelled, it is **passwd**). Then type in the new root password.

```
nayso@Alok-Aspire:~/Desktop$ sudo passwd
[sudo] password for nayso:
Enter new UNIX password:
Retype new UNIX password:
passwd: password updated successfully
nayso@Alok-Aspire:~/Desktop$ su
Password:
root@Alok-Aspire:/home/nayso/Desktop#
```

5. df — Use the **df** command to see the available disk space in each of the partitions in your system. You can just type in **df** in the command line and you can see each mounted partition and their used/available space in % and in KBs. If you want it shown in megabytes, you can use the command "**df** -**m**".

```
root@Alok-Aspire:/home/nayso/Desktop# df -m
Filesystem
              1M-blocks Used Available Use% Mounted on
                                            1% /dev
udev
                     940
                             1
                                      940
tmpfs
                     191
                              2
                                      189
                                            1% /run
/dev/sda5
                   96398 23466
                                    68013
                                           26% /
none
                       1
                             0
                                        1
                                            0% /sys/fs/cgroup
                                            0% /run/lock
                       5
                             0
                                        5
none
                                            1% /run/shm
none
                     951
                              1
                                      950
                             1
                                      100
                                            1% /run/user
                     100
none
```

6. du — Use **du** to know the disk usage of a file in your system. If you want to know the disk usage for a particular folder or file in Linux, you can type in the command **df** and the name of the folder or file. For example, if you want to know the disk space used by the documents folder in Linux, you can use the command "**du Documents**". You can also use the command "**ls -lah**" to view the file sizes of all the files in a folder.

nayso@Alok-Aspire:~\$ du Documents 516 Documents/DIYHacking

548 Documents

7. tar — Use tar to work with tarballs (or files compressed in a tarball archive) in the Linux command line. It has a long list of uses. It can be used to compress and uncompress different types of tar archives like .tar, .tar.gz, .tar.bz2,etc. It works on the basis of the arguments given to it. For example, "tar -cvf" for creating a .tar archive, -xvf to untar a tar archive, -tvf to list the contents of the archive, etc. Since it is a wide topic, here are some examples of tar commands.

8. zip, unzip — Use **zip** to compress files into a zip archive, and **unzip** to extract files from a zip archive.

9. uname — Use **uname** to show the information about the system your Linux distro is running. Using the command "**uname -a**" prints most of the information about the system. This prints the kernel release date, version, processor type, etc.

nayso@Alok-Aspire:~\$ uname -a Linux Alok-Aspire 4.4.0-22-generic #40~14.04.1-Ubuntu SMP Fri May 13 17:27:18 UT C 2016 i686 i686 i686 GNU/Linux

10. apt-get — Use apt to work with packages in the Linux command line. Use apt-get to install packages. This requires root privileges, so use the sudo command with it. For example, if you want to install the text editor jed (as I mentioned earlier), we can type in the command "sudo apt-get install jed". Similarly, any packages can be installed like this. It is good to update your repository each time you try to install a new package. You can do that by typing "sudo apt-get update". You can upgrade the system by typing "sudo apt-get upgrade". We can also upgrade the distro by typing "sudo apt-get dist-upgrade". The command "apt-cache search" is used to search for a package. If you want to search for one, you can type in "apt-cache search jed" (this doesn't require root).

```
nayso@Alok-Aspire:~$ sudo apt-get install jed
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following extra packages will be installed:
    jed-common libslang2-modules slsh
Suggested packages:
    gpm
The following NEW packages will be installed:
    jed jed-common libslang2-modules slsh
0 upgraded, 4 newly installed, 0 to remove and 419 not upgraded.
Need to get 810 kB of archives.
After this operation, 2,992 kB of additional disk space will be used.
Do you want to continue? [Y/n]
```

11. chmod — Use chmod to make a file executable and to change the permissions granted to it in Linux. Imagine you have a python code named numbers.py in your computer. You'll need to run "python numbers.py" every time you need to run it. Instead of that, when you make it executable, you'll just need to run "numbers.py" in the terminal to run the file. To make a file executable, you can use the command "chmod +x numbers.py" in this case. You can use "chmod 755 numbers.py" to give it root permissions or "sudo chmod +x numbers.py" for root executable. Here is some more information about the chmod command.

```
nayso@Alok-Aspire:~/Desktop$ ls
numbers.py
nayso@Alok-Aspire:~/Desktop$ chmod +x numbers.py
nayso@Alok-Aspire:~/Desktop$ ls
numbers.py
```

12. hostname — Use **hostname** to know your name in your host or network. Basically, it displays your hostname and IP address. Just typing "**hostname**" gives the output. Typing in "**hostname -I**" gives you your IP address in your network.

```
nayso@Alok-Aspire:~/Desktop$ hostname
Alok-Aspire
nayso@Alok-Aspire:~/Desktop$ hostname -I
192.168.1.36
```

13. ping — Use **ping** to check your connection to a server. Wikipedia says, "**Ping** is a computer network administration software utility used to test the reachability of a host on an Internet Protocol (IP) network". Simply, when you type in, for example, "**ping google.com**", it checks if it can connect to the server and

come back. It measures this round-trip time and gives you the details about it. The use of this command for simple users like us is to check your internet connection. If it pings the Google server (in this case), you can confirm that your internet connection is active!

```
nayso@Alok-Aspire:~/Desktop$ ping google.com
PING google.com (172.217.26.206) 56(84) bytes of data.
64 bytes from google.com (172.217.26.206): icmp_seq=1 ttl=56 time=51.2 ms
64 bytes from google.com (172.217.26.206): icmp_seq=2 ttl=56 time=47.9 ms
64 bytes from google.com (172.217.26.206): icmp_seq=3 ttl=56 time=48.9 ms
^C
--- google.com ping statistics ---
3 packets transmitted, 3 received, 0% packet loss, time 2000ms
rtt min/avg/max/mdev = 47.959/49.388/51.299/1.417 ms
```

Tips and Tricks for Using Linux Command Line

- You can use the **clear** command to clear the terminal if it gets filled up with too many commands.
- **TAB** can be used to fill up in terminal. For example, You just need to type "**cd Doc**" and then **TAB** and the terminal fills the rest up and makes it "**cd Documents**".
- **Ctrl+C** can be used to stop any command in terminal safely. If it doesn't stop with that, then **Ctrl+Z** can be used to force stop it.
- You can exit from the terminal by using the **exit** command.
- You can power off or reboot the computer by using the command **sudo halt** and **sudo reboot**.
